

Molar Mass:

6.02×10^{23}

- ✓ Molar mass is the mass of one mole of a substance.
- ✓ The molar mass for an atom can be found on the periodic table under the title **atomic molar mass**
- ✓ The units for molar mass are grams per mole or **g/mol**

- ✓ To calculate the molar mass of a compound you have to add up the atomic molar mass of all atoms in that compound.

Ex. What is the molar mass of $\text{CH}_4(\text{g})$?

C = $1 \times 12.01 \text{g/mol} = 12.01 \text{g/mol}$

H = $4 \times 1.01 \text{g/mol} = 4.04 \text{g/mol}$

$\text{CH}_4 = 16.05 \text{g/mol}$

1 mole of methane molecules have a mass of 16.05 grams.

Ex. What is the molar mass of silver chloride?

$M = 107.87 \text{g/mol} + 35.45 \text{g/mol}$

$M = 143.32 \text{g/mol}$

Ex. What is the molar mass of sodium carbonate?

$$\begin{array}{r}
 2 \times 22.99 \text{g/mol} \\
 1 \times 12.01 \text{g/mol} \\
 3 \times 16.00 \text{g/mol} \\
 \hline
 105.99 \text{g/mol}
 \end{array}$$

$$\begin{array}{r}
 2 \times \text{N} = 28.02 \text{g/mol} \\
 8 \times \text{H} = 8.08 \text{g/mol} \\
 1 \times \text{S} = 32.07 \text{g/mol} \\
 4 \times \text{O} = 64.00 \text{g/mol} \\
 \hline
 132.17 \text{g/mol}
 \end{array}$$

$\text{Cu}^{2+} \text{OH}^-$
Copper (II) hydroxide

$$\begin{array}{r}
 1 \times \text{Cu} = 63.55 \text{g/mol} \\
 2 \times \text{O} = 32.00 \text{g/mol} \\
 2 \times \text{H} = 2.02 \text{g/mol} \\
 \hline
 97.57 \text{g/mol}
 \end{array}$$

Relating Moles, Molar Mass and Mass of a substance:

✓ A mathematical formula is used to link Moles, molar mass and mass of a substance

$$m = n \times M$$

$$\begin{aligned} m &= \text{mass (g)} \\ n &= \text{number of moles (mol)} \\ M &= \text{molar mass (g/mol)} \end{aligned}$$

Example: How many moles of silicon are in a 56.18g of silicon?

Step 1: Find out the molar mass of silicon

$$\text{Molar mass of silicon (Si)} = 28.09 \text{ g/mol}$$

Step 2: Rearrange the formula to solve for the unknown

$$\begin{aligned} m &= n \times M \\ n &= \frac{m}{M} \end{aligned} \qquad \frac{56.18 \text{ g}}{28.09 \text{ g/mol}} = \frac{(n) \times (28.09 \text{ g/mol})}{28.09 \text{ g/mol}}$$

Step 3: Calculate the answer

$$n = \frac{56.18 \text{ g}}{28.09 \text{ g/mol}} = 2.000 \text{ mol}$$

Example: What is the mass of 10.0 mol of water?

$$\begin{aligned} n &= 10.0 \text{ mol} \\ M &= 18.02 \text{ g/mol} \\ m &=? \end{aligned} \qquad \begin{aligned} m &= nM \\ m &= (10.0 \text{ mol})(18.02 \text{ g/mol}) \\ &= 180.2 \text{ g} = \boxed{180 \text{ g}} \end{aligned}$$

Example: How many moles are in 15.5 g of iron?

$$\begin{aligned} m &= 15.5 \text{ g} \\ M &= 55.85 \text{ g/mol} \\ n &=? \end{aligned} \qquad \begin{aligned} m &= nM \\ 15.5 \text{ g} &= n(55.85 \text{ g/mol}) \end{aligned} \qquad \begin{aligned} n &= \frac{15.5 \text{ g}}{55.85 \text{ g/mol}} \\ &= 0.2775 \dots \text{ mol} \\ &= \boxed{0.278 \text{ mol}} \end{aligned}$$

$$1 \text{ mol of Fe} = 6.02 \times 10^{23} \text{ atoms (avogadro's number)} \quad \neq$$

$$\# \text{ of atoms/molecules} = (\text{moles}) \times \left(\text{avogadro's } \neq \right. \\ \left. 6.02 \times 10^{23} \right)$$
